

Social Engineering Fraud Training & Simulation Framework

One-month cybersecurity course project | 6-person syndicate | Interactive, measurable and safe

THE PROBLEM

People receive **normal and harmful messages in the same apps**. Attackers use urgency, trust, fear, rewards or authority to make a person act before thinking. A rushed click, reply or download can expose passwords, money or organizational data.

Static lectures explain the risk. This project lets the learner practise the decision.

THE PROJECT IDEA

A browser-based training space presents **randomized, realistic-looking simulations** of email, WhatsApp, Instagram, Telegram, SMS and similar channels. Each item may be legitimate or malicious. The learner inspects it, selects a safe action and immediately learns why the choice was right or wrong.

Core promise: learn to pause, verify and protect - without any real phishing.

1 Four simple objectives

Practice first. Explain immediately. Measure improvement.

01 Recognize

Spot unusual senders, urgent wording, strange links and requests for secrets.

02 Decide

Choose mark safe, ignore, report, block or verify through a trusted channel.

03 Understand

See the attack type, warning signs, likely impact, spread and prevention.

04 Improve

Use scores, feedback and repeated random practice to build safer habits.

2 Example scenario: message to decision

Legitimate items are mixed in so learners cannot simply report everything.

W SIMULATED WHATSAPP

IT Support

Your account expires today. Confirm now at [secure-check.training.example](#) and send the code you receive.

Synthetic sender | Non-working training link

YOUR ACTION

MARK SAFE

IGNORE

REPORT

BLOCK

VERIFY

CORRECT RESPONSE

Report + block, then verify with the real IT team using a known number or portal.

Warning signs

- Urgent deadline
- Unverified support identity
- Request for a one-time code
- Link is not an approved portal

Risk: account takeover may spread the same lure to trusted contacts.

3 The user training loop

Every round creates a short learn-practise-improve cycle.

1 DRAW

Random safe or harmful scenario

2 INSPECT

Read sender, text, link and context

3 ACT

Safe / ignore / report / block / verify

4 FEEDBACK

Right or wrong, score and reasons

5 LEARN

Attack, impact, spread and prevention

Repeat with a new randomized scenario

SAFETY BOUNDARY

This is a **defensive education sandbox**. It uses fictional people, synthetic messages, reserved example domains and non-working links. It sends nothing to real users, stores no real passwords or one-time codes, and never asks a learner to enter genuine credentials.

What We Build in Four Weeks

A small but complete prototype: scenario-rich, explainable, measurable and ready to demonstrate

4 High-level framework architecture

Each layer can be built and tested separately, then connected.

5 Four-week delivery plan

Build the minimum working path early; enrich and polish after it works.

6 Suggested roles for six members

Everyone also writes scenarios and tests another member's work.
